Magnets have two ends – poles – called north and south. Like poles repel; unlike poles attract. BUT magnetic poles ARE DIFFERENT from charges. Charges can be isolated, but magnetic poles CANNOT. You cut a magnet and get two smaller magnets. Magnetic monopoles DO NOT exist.

compass needle = bar magnet, points North.

Iron and few other materials show strong magnetic effects. They are called ferromagnetic (Fe, Co, Ni)

We can think of a magnetic field surrounding a magnet, just like an electric field surrounds an electric charge.
Magnetic Fields

Magnetic fields can be visualized using magnetic field lines, which are always closed loops. Force = interaction between one magnet and magnetic field of the other.

Direction = direction that the north pole of compass points

The Earth’s magnetic field is similar to that of a bar magnet.

Note that the Earth’s “North Pole” is really a south magnetic pole, as the north ends of the compass is attracted to it.

Earth’s poles move in time and even reverse direction

SOLAR WIND:
http://www.teachersdomain.org/resource/ess05.sci.ess.eiu.solarwind/
Electric Current-Magnetic Fields

Experiment shows that, just like magnets, electric current produces a magnetic field.

The direction of the field is given by a right-hand rule.
Electric Current-Magnetic Fields

Compass around wire.

Therefore, electric current (by creating a magnetic field around it) exerts force on magnet.
Electric Current-Magnetic Fields

If electric current exerts force on magnet.

From 3\textsuperscript{rd} law: magnet must exert force on current

\( F \) is perpendicular to \( I, B \)
The force on the wire depends on the current, the length of the wire, the magnetic field, and its orientation.

\[ F_B = iLB \sin \phi \]

This equation defines the magnetic field \( B \).

Maximum and minimum force depend on angle.

Unit of \( B \): the tesla, T. (SI)

1 T = 1 N/A·m.

the gauss (G). In CGS

1 G = 10^{-4} T.

Ex. A wire carrying a 30-A current has length 12 cm between the pole faces of a magnet at an angle of 60°. The magnetic field is approximately uniform at 0.90 T. We ignore the field beyond the pole pieces. What is the magnitude of the force on the wire?

2.8N
The force on the wire depends on the current, the length of the wire, the magnetic field, and its orientation.

\[ F_B = iLB \sin \phi \]

Unit of B: the tesla, T. (SI)
\[ 1 \text{ T} = 1 \text{ N/A} \cdot \text{m}. \]

Convention for magnetic field pointing out of page and into the page.
Ex. 20-2 A rectangular loop of wire hangs vertically as in the figure. A magnetic field is directed horizontally, perpendicular to the wire, and points out of the page at all points. The magnetic field is almost uniform. The top portion of the wire loop is free of the field. The loop hangs from a balance which measures a downward force (besides the gravitational force) of $3.48 \times 10^{-2}$ N when the wire carries $I=0.245$ A. What is the magnitude of the magnetic field $B$?

1.42 T
Magnetic force on a wire carrying current

A straight, horizontal length of copper wire has a current \( i = 28 \) A through it. What are the magnitude and direction of the minimum magnetic field \( \vec{B} \) needed to suspend the wire—that is, to balance the gravitational force on it? The linear density (mass per unit length) of the wire is 46.6 g/m.

**KEY IDEAS**

1. Because the wire carries a current, a magnetic force \( \vec{F}_B \) can act on the wire if we place it in a magnetic field \( \vec{B} \). To balance the downward gravitational force \( \vec{F}_g \) on the wire, we want \( \vec{F}_B \) to be directed upward (Fig. 28-17). (2) The direction of \( \vec{F}_B \) is related to the directions of \( \vec{B} \) and the wire’s length vector \( \vec{L} \) by Eq. 28-26 (\( \vec{F}_B = i\vec{L} \times \vec{B} \)).

**Calculations:** Because \( \vec{L} \) is directed horizontally (and the current is taken to be positive), Eq. 28-26 and the right-hand rule for cross products tell us that \( \vec{B} \) must be horizontal and rightward (in Fig. 28-17) to give the required upward \( \vec{F}_B \).

The magnitude of \( \vec{F}_B \) is \( F_B = iLB \sin \phi \) (Eq. 28-27). Because we want \( \vec{F}_B \) to balance \( \vec{F}_g \), we want

\[
iLB \sin \phi = mg,
\]

(28-29)

where \( mg \) is the magnitude of \( \vec{F}_g \) and \( m \) is the mass of the wire.

**Fig. 28-17** A wire (shown in cross section) carrying current out of the page.

We also want the minimal field magnitude \( B \) for \( \vec{F}_B \) to balance \( \vec{F}_g \). Thus, we need to maximize \( \sin \phi \) in Eq. 28-29. To do so, we set \( \phi = 90^\circ \), thereby arranging for \( \vec{B} \) to be perpendicular to the wire. We then have \( \sin \phi = 1 \), so Eq. 28-29 yields

\[
B = \frac{mg}{iL \sin \phi} = \frac{(m/L)g}{i}.
\]

(28-30)

We write the result this way because we know \( m/L \), the linear density of the wire. Substituting known data then gives us

\[
B = \frac{(46.6 \times 10^{-3} \text{ kg/m})(9.8 \text{ m/s}^2)}{28 \text{ A}}
\]

\[= 1.6 \times 10^{-2} \text{ T}. \]

(Answer)

This is about 160 times the strength of Earth’s magnetic field.
The force on a moving charge is related to the force on a current:

\[ F_B = iLB \sin \phi \]

\[ \frac{Nq}{t}LB \sin \phi = NqvB \sin \phi \]

\[ F_B = |q|vB \sin \phi \]

\[ \vec{F}_B = q\vec{v} \times \vec{B} \]

Once again, the direction is given by a right-hand rule.

NOTE: electron position is opposite to the current.
Ex. A proton having a speed of $5.0 \times 10^6 \text{m/s}$ in a magnetic field feels a force of $8.0 \times 10^{-14} \text{N}$ toward the west when it moves vertically upward. When moving horizontally in a northerly direction, it feels zero force. Determine the magnitude and direction of the magnetic field in this region ($q=+e=1.6 \times 10^{-19} \text{C}$)

If a charged particle is moving perpendicular to a uniform magnetic field, its path will be a circle. \(a=v^2/r\)

Ex. An electron travels at $2.0 \times 10^7 \text{m/s}$ in a plane perpendicular to a uniform 0.010-T magnetic field. What is the radius of the electron motion?

\[ m=9.1 \times 10^{-31} \text{kg} \]

1.1 cm
Uniform circular motion of a charged particle in a magnetic field

Figure 28-12 shows the essentials of a mass spectrometer, which can be used to measure the mass of an ion; an ion of mass \( m \) (to be measured) and charge \( q \) is produced in source \( S \). The initially stationary ion is accelerated by the electric field due to a potential difference \( V \). The ion leaves \( S \) and enters a separator chamber in which a uniform magnetic field \( B \) is perpendicular to the path of the ion. A wide detector lines the bottom wall of the chamber, and the \( B \) causes the ion to move in a semicircle and thus strike the detector. Suppose that \( B = 80.000 \text{ mT}, V = 1000.0 \text{ V}, \) and ions of charge \( q = +1.6022 \times 10^{-19} \text{ C} \) strike the detector at a point that lies at \( x = 1.6254 \text{ m} \). What is the mass \( m \) of the individual ions, in atomic mass units (Eq. 1-7: \( 1 \text{ u} = 1.6605 \times 10^{-27} \text{ kg} \))?

**KEY IDEAS**

1. Because the (uniform) magnetic field causes the (charged) ion to follow a circular path, we can relate the ion’s mass \( m \) to the path’s radius \( r \) with Eq. 28-16 \( r = \frac{mv}{qlB} \). From Fig. 28-12 we see that \( r = x/2 \) (the radius is half the diameter). From the problem statement, we know the magnitude \( B \) of the magnetic field. However, we lack the ion’s speed \( v \) in the magnetic field after the ion has been accelerated due to the potential difference \( V \).

Finding speed: When the ion emerges from the source, its kinetic energy is approximately zero. At the end of the acceleration, its kinetic energy is \( \frac{1}{2}mv^2 \). Also, during the acceleration, the positive ion moves through a change in potential of \(-V\). Thus, because the ion has positive charge \( q \), its potential energy changes by \(-qV\). If we now write the conservation of mechanical energy as

\[
\Delta K + \Delta U = 0,
\]

we get

\[
\frac{1}{2}mv^2 - qV = 0
\]

or

\[
v = \sqrt{\frac{2qV}{m}}.
\]  (28-22)

Finding mass: Substituting this value for \( v \) into Eq. 28-16 gives us

\[
r = \frac{mv}{Bq} = \frac{m}{Bq} \sqrt{\frac{2qV}{m}} = \frac{1}{B} \sqrt{\frac{2mV}{q}}.
\]

Thus,

\[
x = 2r = \frac{2}{B} \sqrt{\frac{2mV}{q}}.
\]

Solving this for \( m \) and substituting the given data yield

\[
m = \frac{B^2qx^2}{8V} = \frac{(0.08000 \text{ T})(1.6022 \times 10^{-19} \text{ C})(1.6254 \text{ m})^2}{8(1000.0 \text{ V})} = 3.3863 \times 10^{-25} \text{ kg} = 203.93 \text{ u}.
\]  (Answer)

</table>
The magnetic field due to a long wire is given by the formula:

\[ B = \frac{\mu_0 I}{2\pi r} \]

where \( B \) is the magnetic field, \( I \) is the current, \( \mu_0 \) is the permeability of free space, and \( r \) is the distance from the wire.

The constant \( \mu_0 \) is called the permeability of free space, and has the value:

\[ \mu_0 = 4\pi \times 10^{-7} \text{T} \cdot \text{m/A} \]

Example: An electric wire in the wall of a building carries a dc current of 25 A vertically upward. What is the magnetic field due to this current at a point P 10 cm due north of the wire?

\[ B = 5.0 \times 10^{-5} \text{T} \]
Magnetic Field due to long Wire

The field is inversely proportional to the distance from the wire:

\[ B = \frac{\mu_0 I}{2\pi r} \]

The constant \( \mu_0 \) is called the permeability of free space, and has the value:

\[ \mu_0 = 4\pi \times 10^{-7} \text{ T} \cdot \text{m/A} \]

Ex. Two parallel straight wires 10.0 cm apart carry currents in opposite directions. Current \( I_1 = 5.0 \text{ A} \) is out of the page and \( I_2 = 7.0 \text{ A} \) is into the page. Determine the magnitude and direction of the magnetic field halfway between the two wires.

\[ B = 4.8 \times 10^{-5} \text{ T} \]

up
Force between two parallel wires
Force between two parallel wires

The magnetic field produced at the position of wire 2 due to the current in wire 1 is:

\[ B_1 = \frac{\mu_0 I_1}{2\pi d} \]

The force this field exerts on a length \( l_2 \) of wire 2 is:

\[ F_2 = B_1 I_1 l_2 \]

Parallel currents attract; antiparallel currents repel.
Ex. The two wires of a 2.0-m long appliance cord are 3.0 mm apart and carry a current of 8.0 A dc. Calculate the force one wire exerts on the other.

\[ F = 8.5 \times 10^{-3} \text{ N} \]

Ex. A horizontal wire carries a current \( I_1 = 80 \text{ A dc} \). A second parallel wire 20 cm below it must carry how much current \( I_2 \) so that it does not fall due to gravity? The lower wire has mass of 0.12 g per meter of length.

\[ I_2 = 15 \text{ A} \]
Figure 29-8a shows two long parallel wires carrying currents \( i_1 \) and \( i_2 \) in opposite directions. What are the magnitude and direction of the net magnetic field at point \( P \)? Assume the following values: \( i_1 = 15 \, \text{A} \), \( i_2 = 32 \, \text{A} \), and \( d = 5.3 \, \text{cm} \).

**KEY IDEAS**

1. The net magnetic field \( \vec{B} \) at point \( P \) is the vector sum of the magnetic fields due to the currents in the two wires.
2. We can find the magnetic field due to any current by applying the Biot–Savart law to the current. For points near the current in a long straight wire, that law leads to Eq. 29.4.

**Finding the vectors:** In Fig. 29-8a, point \( P \) is distance \( R \) from both currents \( i_1 \) and \( i_2 \). Thus, Eq. 29.4 tells us that at point \( P \) those currents produce magnetic fields \( \vec{B}_1 \) and \( \vec{B}_2 \) with magnitudes

\[
\vec{B}_1 = \frac{\mu_0 i_1}{2\pi R} \quad \text{and} \quad \vec{B}_2 = \frac{\mu_0 i_2}{2\pi R}.
\]

In the right triangle of Fig. 29-8a, note that the base angles (between sides \( R \) and \( d \)) are both 45°. This allows us to write \( \cos 45° = \frac{R}{d} \) and replace \( R \) with \( d \cos 45° \). Then the field magnitudes \( B_1 \) and \( B_2 \) become

\[
B_1 = \frac{\mu_0 i_1}{2\pi d \cos 45°} \quad \text{and} \quad B_2 = \frac{\mu_0 i_2}{2\pi d \cos 45°}.
\]

![Diagram of two parallel wires with magnetic fields](image)

The two currents create magnetic fields that must be added as vectors to get the net field.

**Fig. 29-8** (a) Two wires carry currents \( i_1 \) and \( i_2 \) in opposite directions (out of and into the page). Note the right angle at \( P \). (b) The separate fields \( \vec{B}_1 \) and \( \vec{B}_2 \) are combined vectorially to yield the net field \( \vec{B} \).

We want to combine \( \vec{B}_1 \) and \( \vec{B}_2 \) to find their vector sum, which is the net field \( \vec{B} \) at \( P \). To find the directions of \( \vec{B}_1 \) and \( \vec{B}_2 \), we apply the right-hand rule of Fig. 29-4 to each current in Fig. 29-8a. For wire 1, with current out of the page, we mentally grasp the wire with the right hand, with the thumb pointing out of the page. Then the curled fingers indicate that the field lines run counterclockwise. In particular, in the region of point \( P \), they are directed upward to the left. Recall that the magnetic field at a point near a long, straight current-carrying wire must be directed perpendicular to a radial line between the point and the current. Thus, \( \vec{B}_1 \) must be directed upward to the left as drawn in Fig. 29-8b. (Note carefully the perpendicular symbol between vector \( \vec{B}_1 \) and the line connecting point \( P \) and wire 1.)

Repeating this analysis for the current in wire 2, we find that \( \vec{B}_2 \) is directed upward to the right as drawn in Fig. 29-8b. (Note the perpendicular symbol between vector \( \vec{B}_2 \) and the line connecting point \( P \) and wire 2.)

**Adding the vectors:** We can now vectorially add \( \vec{B}_1 \) and \( \vec{B}_2 \) to find the net magnetic field \( \vec{B} \) at point \( P \), either by using a vector-capable calculator or by resolving the vectors into components and then combining the components of \( \vec{B} \). However, in Fig. 29-8b, there is a third method: Because \( \vec{B}_1 \) and \( \vec{B}_2 \) are perpendicular to each other, they form the legs of a right triangle, with \( \vec{B} \) as the hypotenuse. The Pythagorean theorem then gives us

\[
B = \sqrt{B_1^2 + B_2^2} = \frac{\mu_0}{2\pi d (\cos 45°)} \sqrt{i_1^2 + i_2^2}
\]

\[
= (4\pi \times 10^{-7} \, \text{T} \cdot \text{m/A}) \sqrt{(15 \, \text{A})^2 + (32 \, \text{A})^2}
\]

\[
= \frac{(2\pi)(5.3 \times 10^{-2} \, \text{m})(\cos 45°)}{2}(18.7 \times 10^{-4} \, \text{T} - 190 \, \mu\text{T}).
\]

The angle \( \phi \) between the directions of \( \vec{B} \) and \( \vec{B}_2 \) in Fig. 29-8b follows from

\[
\phi = \tan^{-1} \left( \frac{B_1}{B_2} \right),
\]

which, with \( B_1 \) and \( B_2 \) as given above, yields

\[
\phi = \tan^{-1} \left( \frac{15}{32} \right) = \tan^{-1} \left( \frac{15 \, \text{A}}{32 \, \text{A}} \right) = 20°.
\]

The angle between the direction of \( \vec{B} \) and the \( x \) axis shown in Fig. 29-8b is then

\[
\phi + 45° = 20° + 45° = 65°.
\]
Law of Biot and Savart

\[ d\vec{B} = \frac{\mu_0}{4\pi} \frac{i \, ds \times \hat{r}}{r^2} \]  

\[ \mu_0 = 4\pi \times 10^{-7} \text{T} \cdot \text{m/A} \]

\[ dB = \frac{\mu_0}{4\pi} \frac{i \, ds \sin \theta}{r^2} \]

Magnetic Field Due to a Current in a Long Straight Wire

\[ B = \frac{\mu_0 i}{2\pi R} \]
The magnetic field produced at P by the current-length elements in the upper half of the infinitely long wire can be obtained by integrating $dB$ from 0 to $\infty$.

The magnetic field produced by the lower half of the wire is exactly the same as that produced by the upper half, so

$$B = 2 \int_0^\infty dB = \frac{\mu_0 i}{2\pi} \int_0^\infty \frac{\sin \theta \, ds}{r^2}$$

$$r = \sqrt{s^2 + R^2}$$

$$\sin \theta = \sin(\pi - \theta) = \frac{R}{\sqrt{s^2 + R^2}}$$
Magnetic Field Due to a Current in a Long Straight Wire

This element of current creates a magnetic field at $P$, into the page.

$$B = 2\int_0^\infty dB = \frac{\mu_0 i}{2\pi} \int_0^\infty \frac{\sin \theta \, ds}{r^2}$$

$$r = \sqrt{s^2 + R^2}$$

$$\sin \theta = \sin(\pi - \theta) = \frac{R}{\sqrt{s^2 + R^2}}$$

$$B = \frac{\mu_0 i}{2\pi} \int_0^\infty \frac{R \, ds}{(s^2 + R^2)^{3/2}}$$

$$= \frac{\mu_0 i}{2\pi R} \left[ \frac{s}{(s^2 + R^2)^{1/2}} \right]_0^\infty = \frac{\mu_0 i}{2\pi R}$$

$$B = \frac{\mu_0 i}{2\pi R}$$
Magnetic Field Due to a Current in a Circular Arc of Wire

No matter where the element $\mathbf{ds}$ is located on the wire, the angle $\phi$ between the vectors $\mathbf{ds}$ and $\hat{r}$ is $90^\circ$.

$$dB = \frac{\mu_0}{4\pi} \frac{i \, ds \sin \theta}{r^2}$$

The total field at $C$ is simply the sum (via integration) of all the differential fields $d\mathbf{B}$.

To solve the integral below, we use the definition of radians, that is

$$ds = R \, d\phi$$

$$B = \int dB = \int_0^\phi \frac{\mu_0}{4\pi} \frac{iR \, d\phi}{R^2} = \frac{\mu_0 i}{4\pi R} \int_0^\phi d\phi$$

$$B = \frac{\mu_0 i \phi}{4\pi R}$$
Magnetic Field Due to a Current in a Circular Arc of Wire

\[ B = \frac{\mu_0 i \phi}{4\pi R} \]

Note that this equation gives us the magnetic field only at the center of curvature of a circular arc of current. When you insert data into the equation, you must be careful to express \( \phi \) in radians rather than degrees. For example, to find the magnitude of the magnetic field at the center of a full circle of current, you would substitute \( \phi \) with \( 2\pi \)

\[ B = \frac{\mu_0 i (2\pi)}{4\pi R} = \frac{\mu_0 i}{2R} \]
Sample Problem

Magnetic field at the center of a circular arc of current

The wire in Fig. 29-7a carries a current \( i \) and consists of a circular arc of radius \( R \) and central angle \( \pi/2 \) rad, and two straight sections whose extensions intersect the center \( C \) of the arc. What magnetic field \( \vec{B} \) (magnitude and direction) does the current produce at \( C \)?

Current directly toward or away from \( C \) does not create any field there.

\[
\begin{align*}
B_1 &= 0 \\
B_2 &= 0 \\
B_3 &= \frac{\mu_0 i (\pi/2)}{4\pi R} = \frac{\mu_0 i}{8R}
\end{align*}
\]

\( \vec{B} = \vec{B}_3 \)

Fig. 29-7  
(a) A wire consists of two straight sections (1 and 2) and a circular arc (3), and carries current \( i \). (b) For a current-length element in section 1, the angle between \( d\vec{s} \) and \( \hat{r} \) is zero. (c) Determining the direction of magnetic field \( \vec{B}_3 \) at \( C \) due to the current in the circular arc; the field is into the page there.
\[ \oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 i_{\text{enc}} \]  
(Ampere’s law).

(29-14)

The loop on the integral sign means that the scalar (dot) product \( \mathbf{B} \cdot d\mathbf{s} \) is to be integrated around a *closed* loop, called an *Amperian loop*. The current \( i_{\text{enc}} \) is the net current encircled by that closed loop.

We can now interpret the scalar product \( \mathbf{B} \cdot d\mathbf{s} \) as being the product of a length \( ds \) of the Amperian loop and the field component \( B \cos \theta \) tangent to the loop. Then we can interpret the integration as being the summation of all such products around the entire loop.
Ampere’s Law

\[ \oint \vec{B} \cdot d\vec{s} = \mu_0 i_{\text{enc}} \]  \hspace{1cm} (Ampere’s law). \hspace{1cm} (29-14)

The loop on the integral sign means that the scalar (dot) product \( \vec{B} \cdot d\vec{s} \) is to be integrated around a closed loop, called an Amperian loop. The current \( i_{\text{enc}} \) is the net current encircled by that closed loop.

**Fig. 29-13** Using Ampere’s law to find the magnetic field that a current \( i \) produces outside a long straight wire of circular cross section. The Amperian loop is a concentric circle that lies outside the wire.

All of the current is encircled and thus all is used in Ampere's law.

\[ \oint \vec{B} \cdot d\vec{s} = \oint B \cos \theta \, ds = B \oint ds = B(2\pi r) \]

\[ B(2\pi r) = \mu_0 i \]

\[ B = \frac{\mu_0 i}{2\pi r} \]  (outside straight wire)
8. An electric field of 1.50 kV/m and a perpendicular magnetic field of 0.400 T act on a moving electron to produce no net force. What is the electron’s speed?

3.75 \times 10^3 \text{ m/s}

9. In Fig. 28-31, an electron accelerated from rest through potential difference \( V_1 = 1.00 \) kV enters the gap between two parallel plates having separation \( d = 20.0 \) mm and potential difference \( V_2 = 100 \) V. The lower plate is at the lower potential. Neglect fringing and assume that the electron’s velocity vector is perpendicular to the electric field vector between the plates. In unit-vector notation, what uniform magnetic field allows the electron to travel in a straight line in the gap?

\[ \vec{B} = -(2.67 \times 10^{-4} \text{ T})\hat{k} \]

Note:
From the figure, the x-direction is to the right, the y-direction is up and the z-direction is out of the page.
Problems: Ch.29

8. In Fig. 29-39, two semicircular arcs have radii $R_2 = 7.80$ cm and $R_1 = 3.15$ cm, carry current $i = 0.281$ A, and share the same center of curvature $C$. What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at $C$?

1.67×10^{-6} T

into the page

10. In Fig. 29-40, a wire forms a semicircle of radius $R = 9.26$ cm and two (radial) straight segments each of length $L = 13.1$ cm. The wire carries current $i = 34.8$ mA. What are the (a) magnitude and (b) direction (into or out of the page) of the net magnetic field at the semicircle's center $C$?

1.18×10^{-7} T

into the page

21. Figure 29-48 shows two very long straight wires (in cross section) that each carry a current of 4.00 A directly out of the page. Distance $d_1 = 6.00$ m and distance $d_2 = 4.00$ m. What is the magnitude of the net magnetic field at point $P$, which lies on a perpendicular bisector to the wires?

2.56×10^{-7} T
